IMPLEMENTING C++ CLASSES

Problem Solving with Computers-II

Read the syllabus. Know what's required. Know how to get help.

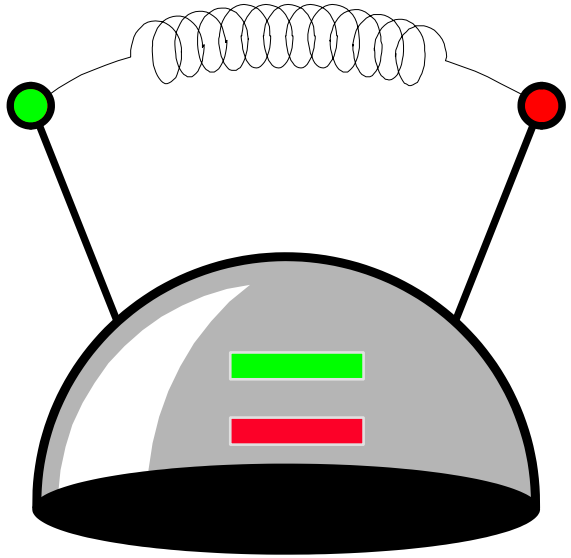
CLICKERS OUT – FREQUENCY AB

Announcements

- Submit CS16 final exam (part of HW 1) tomorrow in sections
- If you want to pair with someone in the same section (different mentor group), let your current mentor know asap
- Mentor groups will be finalized by tomorrow.

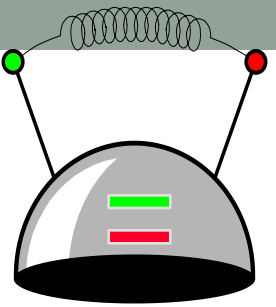
Clickers out – frequency AB

Description of the thinking cap



- You may put a piece of paper in each of the two slots (green and red), with a sentence written on each.
- You may push the green button and the thinking cap will speak the sentence from the green slot's paper.
- And same for the red button.

Review: Thinking Cap Definition

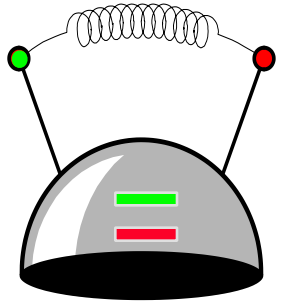


```
class thinking_cap
{
public:
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( );
    void push_red( );
private:
    char green_string[50];
    char red_string[50];
};
```

When are the data members (green_string and red_string) created in memory

A. When the compiler compiles the class definition (above)
B. When an object of type thinking_cap is created in the program (at run-time)
C. When the slots() member function is activated

Thinking Cap Implementation

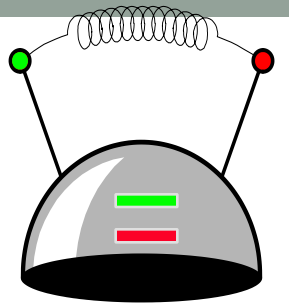


- Usually we implement the class in a separate .cpp file.

```
class thinking_cap
{
public:
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( );
    void push_red( );
private:
    char green_string[50];
    char red_string[50];
};
```

Function bodies will be in .cxx file.

Thinking Cap Implementation

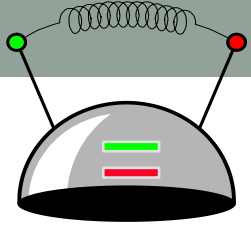


There are two special features about a member function's implementation . . .

```
void thinking_cap::slots(char new_green[ ], char new_red[ ])
{

}
```

Thinking Cap Implementation

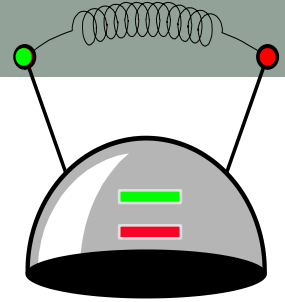


There are two special features about a member function's implementation . . .

1. The class name is included in the function's heading using the :: operator
2. The function can refer to any of the member variables

```
void thinking_cap::slots(char new_green[ ], char new_red[ ])
{
    assert(strlen(new_green) < 50);
    assert(strlen(new_red) < 50);
    strcpy(green_string,  new_green);
    strcpy(red_string, new_red);
}
```

Thinking Cap Implementation



Within the body of the function, the class's member variables and other methods may all be accessed.

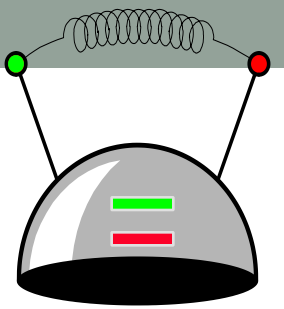
```
void thinking_cap::slots(char new_
{
    assert(strlen(new_green) < 50)
    assert(strlen(new_red) < 50);
    strcpy(green_string,  new_gree
    strcpy(red_string, new_red);
}
```

But, whose member variables are these? Are they

- ***student.green_string***
- ***student.red_string***
- ***fan.green_string***
- ***fan.red_string***

?

Thinking Cap Implementation



Within the body of the function, the class's member variables and other member functions may all be accessed.

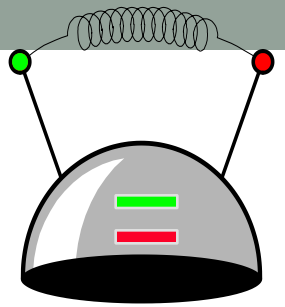
```
void thinking_cap::slots(char new_
{
    assert(strlen(new_green) < 50)
    assert(strlen(new_red) < 50);
    strcpy(green_string,  new_gree
    strcpy(red_string, new_red);
}
```

If we activate student.slots:

student.green_string

student.red_string

Thinking Cap Implementation



Within the body of the function, the class's member variables and other member functions may all be accessed.

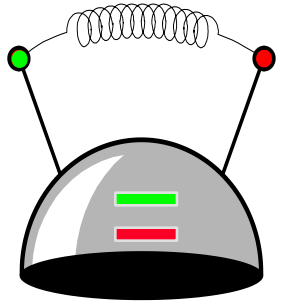
```
void thinking_cap::slots(char new_
{
    assert(strlen(new_green) < 50)
    assert(strlen(new_red) < 50);
    strcpy(green_string,  new_gree
    strcpy(red_string, new_red);
}
```

If we activate fan.slots:

fan.green_string

fan.red_string

Thinking Cap Implementation



Here is the implementation of the push_green() member function, which prints the green message:

```
void thinking_cap::push_green( )
{

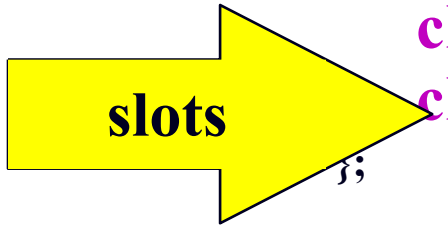
    cout << green_string << endl;

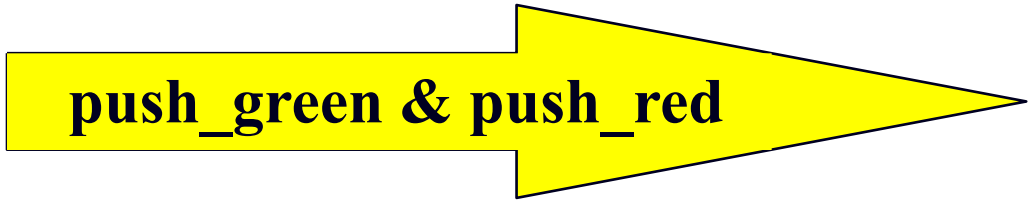
}
```

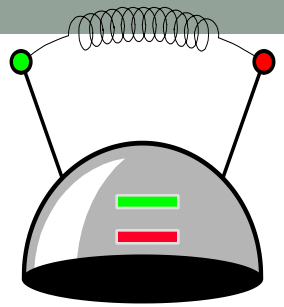
A Common Pattern

- Often, one or more member functions will place data in the member variables...

```
class thinking_cap {
public:
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( ) const;
    void push_red( ) const;
private:
    char green_string[50];
    char red_string[50];
};
```







A Quiz

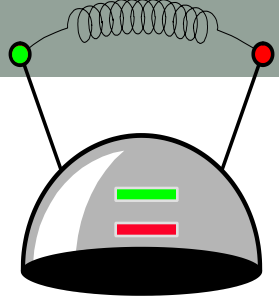
Is the code in main() a permissible usage of the thinking_cap ADT? Discuss why or why not.

A. *Yes*
B. *No*

```
class thinking_cap
{
public:
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( ) const;
    void push_red( ) const;
private:
    char green_string[50];
    char red_string[50];
};

int main( )
{
    thinking_cap student;
    student.push_green( );
}
```

Constructor



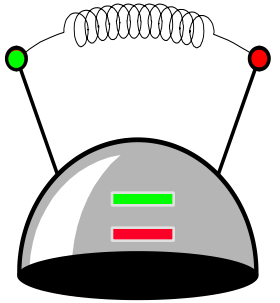
An “initialization” function that is guaranteed to be called when an object of the class is created

```
class thinking_cap
{
public:
    thinking_cap(char new_green[], char new_red[]);
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( ) const;
    void push_red( ) const;
private:
    char green_string[50];
    char red_string[50];
};
```

Which distinction(s) do you see between the constructor and other methods of the class?

A. *The constructor has the same name as the class*
B. *It doesn’t have a return type*
C. *It has formal parameters*
D. *A and B*
E. *None of the above*

Implementation of the constructor



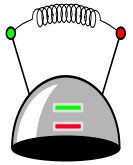
Do you expect the body of the constructor to be different from the slots() method in this example? Discuss with your group why or why not.

A. Yes
B. No

```
thinking_cap::thinking_cap(char new_green[], char new_red[] )
{
    //Code for initializing the member variables of

}
```

Using the constructor

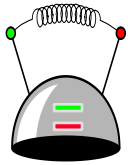


```
class thinking_cap
{
public:
    thinking_cap(char ng[], char nr[]);
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( ) const;
    void push_red( ) const;
private:
    char green_string[50];
    char red_string[50];
};
```

What is the output of this code?

```
int main( )
{
    thinking_cap student("Hello","Goodbye");
    student.push_green( );
}
```

Using the constructor

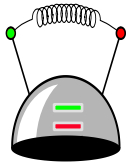


```
class thinking_cap
{
public:
    thinking_cap(char ng[], char nr[]);
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( ) const;
    void push_red( ) const;
private:
    char green_string[50];
    char red_string[50];
};
```

What is the output of this code?

```
int main( )
{
    thinking_cap fan;
    fan.slots("Hi", "There");
    fan.push_green( );
}
```

Need to specify a default constructor



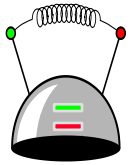
```
class thinking_cap
{
public:

    thinking_cap(char ng[], char nr[]);
     void slots(char new_green[ ], char new_red[ ]);
     void push_green( ) const;
     void push_red( ) const;
private:
     char green_string[50];
     char red_string[50];
};
```

```
int main( ) {
    thinking_cap fan;
    fan.slots("Hi", "There");
    fan.push_green( );
}
```

The main function worked before when we never had a constructor. Why?

Need to specify a default constructor

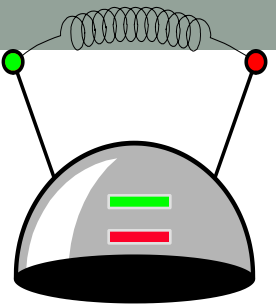


```
class thinking_cap
{
public:
thinking_cap(); //Default constructor
thinking_cap(char ng[], char nr[]); //Parameterized constructor
    void slots(char new_green[ ], char new_red[ ]);
    void push_green( ) const;
    void push_red( ) const;
private:
    char green_string[50];
    char red_string[50];
};
```

Implement the default constructor to give default values to the data members

```
int main( ) {
    thinking_cap fan;
    fan.slots("Hi", "There");
    fan.push_green( );
}
```

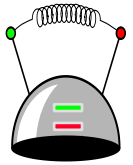
```
class thinking_cap
{
public:
                thinking_cap(); //Default constructor
                thinking_cap(char ng[], char nr[]); //
Parameterized
        void slots(char new_green[ ], char new_red[ ]);
        void push_green( ) const;
        void push_red( ) const;
private:
        char green_string[50];
        char red_string[50];
}
```



When are the data members (green_string and red_string) created in memory

A. When the compiler compiles the class definition (above)
B. When an object of type thinking_cap is created in the program (at run-time)
C. When the constructor explicitly creates these variables.

Value semantics: Assignment



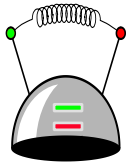
The value semantics of a class determines how values are copied from one object to another.

- Assignment operation
- Copy constructor

What is the output of this code?

```
int main( ) {
    thinking_cap fan;
    thinking_cap student("Hi", "there");
    fan = student;
    fan.push_green( );
}
```

Value semantics: Copy constructor



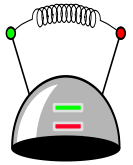
The value semantics of a class determines how values are copied from one object to another.

- Assignment operation
- Copy constructor

What is the output of this code?

```
int main( ) {
   thinking_cap student(“Hi”, “there”);
   thinking_cap fan(student);
   fan.push_green( );
   fan.push_red();
}
```

Operator overloading



We would like to be able to compare two objects of the class using the following operators

==

!=

and possibly others

```
int main( ) {
    ….
    if(fan == student)
      cout<<“Both caps have the same strings”<<endl;

}
```

Summary

- Classes have member variables and member functions (method). An object is a variable where the data type is a class.
- You should know how to declare a new class type, how to implement its member functions, how to use the class type.
- Frequently, the member functions of an class type place information in the member variables, or use information that's already in the member variables.
- In the future we will see more features of OOP.

Next time

- Operator overloading
